Description

FIELD OF THE INVENTION AND RELATED ART STATEMENT

1. FIELD OF THE INVENTION

The present invention relates to a combustion apparatus provided with a function of noise silencing, by which the combustion noise of a small-size combustion apparatus burning gas or others as its fuel is suppressed. The noise suppression is made by a phase interference based on a computation of signal of anti-phase with respect to pressure variations caused by the combustion in accordance with the adaptive type active control.

2. DESCRIPTION OF THE RELATED ART

As a prior art, as shown in a patent USP5145355, there is a conventional example in which noise is suppressed by the active control using a feedback control of pressure variations caused by the combustion. As is shown in FIG.21, signal of pressure variations in a chamber 1 detected by a microphone 5 is delayed by a control means 6, and applied to a monitoring means 8 as an anti-phase signal. At the monitoring means 8, a pressure variation of anti-phase on fuel is generated and mixed with air at a burner part 4, and thereby the pressure variation in the chamber 1 is suppressed by the phase interference.

In the above-mentioned constitution, however, the pressure variations detected by a microphone 5 is only applied to the monitoring means 8 after a time delay, and there is no disclosure on a control for realizing an optimum control effect on pressure variations in the chamber 1 accompanied with a consideration on the pressure propagation characteristics for a range from the monitoring means 8 to the microphone 5. That is, first, it is assumed that a fuel supply line 3 from the monitoring means 8 to the microphone 5 has a pressure propagation characteristic i.e., the acoustic wave propagation characteristics as is shown in FIG.22(a). This graph shows a pressure waveform caused by such as an output characteristic of the monitoring means 8 and a resonance characteristic occurring in a space for a range from the monitoring means 8 to the chamber 1. In the graph of FIG.22(a) the abscissa is graduated with time and the ordinate by pressure level. Even by optimally adjusting the amplitude and the phase of a pressure signal in the chamber 1 detected by the microphone 5 indicated by a broken line in FIG.22(b) by the control means 6 and thereby to minimize the signal detected by the microphone 5 by feeding the above-mentioned optimally adjusted pressure signal indicated by a solid line in FIG.22(b) to the monitoring means 8, a complete cancellation of the pressure variations is difficult. That is, a resulted actual pressure level in the chamber

1 becomes a waveform such as shown in FIG.22(c) on which the pressure propagation characteristics shown by hatchings are superimposed, which propagation characteristics makes complete cancellation of the pressure variations difficult. And associated with the amount of combustion, the frequency characteristics or the output characteristics of the combustion noise make variations or fluctuations, but hitherto there is no disclosure yet on procedure of suppressing the pressure variations with a sufficient accuracy corresponding to those above-mentioned characteristic variations.

As for another working example, there is an art disclosed by a British patent document GB2239961-A concerning an active control, in which the instability of the combustion is suppressed. As is shown in FIG.23, the pressure variation signal detected by a pressure transducer provided in a combustion chamber is amplified and filtered, and thereafter a signal phase-shifted by a phase shifter and amplified by an amplifier is fed to a servo valve. The above-mentioned signal is applied to fuel through the servo valve, and then the pressure variation is transferred to the combustion chamber. Thereby the unstable pressure variation taking place in the combustion chamber is suppressed. In this prior art example, likewise in the aforementioned prior art, consideration is not given on the pressure propagation characteristic for a range from the servo valve to the combustion chamber. This British document makes no disclosure for the control realizing an optimum suppression effect on the pressure variations in the combustion chamber. Neither, a procedure of suppressing the pressure variations with a sufficient accuracy corresponding to the variation associated with the amount of combustion is disclosed yet.

Furthermore, as still another prior art example, Japanese Tokkai in (Unexamined published patent application) JP-A-61-296392 discloses an art that is related to the electronic noise silencing system. The art is such that the noise silencing can be made for a non-steady noise taking place inside a conducting duct (conduit) such as a tubing duct by means of an adaptive control based on an electronic noise silencing system. This is a noise silencing procedure using a feed-forward type adaptive active control exemplified by the active noise control (hereinafter ANC). As is shown in FIG.24 and FIG.25, noise propagating in a conducting duct is detected by a microphone M_1 , and an anti-phase signal is computed based on the detected signal using a controller H_e , then the anti-phase sound is radiated inside the conducting duct by a speaker S provided in the conducting duct, and thereby the noise is suppressed. At this time, the controller H_e adjusts phase and amplitude of the anti-phase sound so as to decrease the signal detected by a microphone M_2 based on the adaptive control rule. And, the output characteristics of the microphone M_2 and the speaker S as well as the acoustic propagation characteristics G_1 from the speaker S to the microphone M_2 is identified as a pressure propagation

characteristic H_t under the state of absence of noise in the conducting duct. This identified pressure propagation characteristic H_t is corrected and processed by the controller H_e , and the resultant signal is issued as a corrected anti-phase signal, thereby to improve the noise silencing effect.

The basic principle of the above-mentioned ANC, however, is the one that takes a constitution of a feed-forward type noise silencing, in which the anti-phase sound is computed and radiated from a speaker S before the arrival of detected noise after propagation. So far there is no prior art using a constitution in which generated noise is suppressed by a feedback fashion. And corrected characteristics are the output characteristics of the microphone M_2 and the speaker S as well as the acoustic propagation characteristics G_t for a range from the speaker S to the microphone M_2 . The corrected pressure propagation characteristics H_t is identified under the state of absence of noise in the conducting duct. Consequently, in case of employing a feedback type control under the situation of presence of noise in the conducting duct in which the sound propagates from speaker S to the microphone M_2 , there is such a problem that the pressure propagation characteristic to be corrected must be identified under the state of presence of noise. Moreover, in order to suppress the generated wide band irregular noise, it is necessary to compute the anti-phase sound by the controller H_e and radiate it through the speaker S before the noise detected by the microphone M_1 arrives at the speaker S after propagation in the conducting duct. Restriction presented by the signal processing capability of the present day art is only up to several msec. Due to this limit, a distance between the microphone M_1 and the speaker S must be more than 1 m, and accordingly it has been said that the suppression of non-steadily continuing noise in a small size home appliances was very difficult.

OBJECT AND SUMMARY OF THE INVENTION

The Japan Patent JP A-3 036 897 discloses an electronic silencing system being able to reduce noise in general by correcting a control parameter. To erase noise it is executed in the process of detecting a noise by a first detector and radiating an anti-phase sound of the detected noise from a speaker. A propagation characteristic from the speaker to a second detector is corrected under the state of absence of noise, and the resultant signal is issued as a corrected anti-phase signal. But, this document does not teach to consider the propagation characteristic under the state of combustion.

In the present invention, a first object is to suppressing the combustion noise largely by making the fuel control means generate pressure variations of anti-phase therefrom and making the pressure interference in a combustion chamber more effective, considering the pressure propagation characteristics i.e., acoustic wave propagation characteristics for a range from a fuel con-

trol means to a pressure detector under the state of combustion; and at the same time to suppress the combustion noise corresponding with a sufficient accuracy to the variations of the combustion noise characteristics by applying the adaptive type active control.

A second object of the present invention is that, by providing an acoustic wave generation means for generating an anti-phase sound in the vicinity of upper side part of an exhaust outlet and providing a second pressure detector between the exhaust outlet and the acoustic wave generation means, a positive-negative doublet sound source is constituted in a manner having the exhaust outlet as a positive sound source and the acoustic generation means as a negative sound source. Thereby, the combustion noise radiated from the exhaust outlet is reduced for all the directions, and at the same time the combustion noise is reduced with a sufficient accuracy corresponding to variations of the combustion noise characteristics.

In order to achieve the above-mentioned objects the apparatuses comprises the features of claims 1, 6, 7 and 8. A first mode of the apparatus of the present invention comprises: a fuel control means for controlling the amount of fuel supply and a pressure detector for detecting pressure variations caused by the combustion, thereby to cancel the pressure variation by phase interference by means of feedback type control wherein an anti-phase signal is produced based on a signal from the pressure detector and the anti-phase signal is applied to the fuel control means, the combustion apparatus further comprising an electric filter for correcting a change of pressure propagation characteristic means for correcting an influence of a pressure propagation characteristics i.e., the acoustic wave propagation characteristics for a range from the fuel control means to the pressure detector under the state of combustion, adaptive processing means for computing an anti-phase signal to obtain pressure variations substantially becoming anti-phase at the position of the pressure detector in accordance with both the signal of the pressure detector and the signal of the pressure detector which has passed through the electric filter for correcting a change of pressure propagation characteristic and means for applying the signal of the adaptive signal processing device to the fuel control means.

In accordance with the above constitution, the electric filter for correcting a change of pressure propagation characteristic realizes a pressure propagation characteristic for a range from the fuel control means to the pressure detector under the state of combustion. As a result, variations of the pressure propagation characteristic due to the combustion, propagation characteristics for a range from the fuel control means to the pressure detector, and an electroacoustical conversion characteristic can be corrected. Thereby the combustion noise can be reduced largely by generating an anti-phase sound accurately. Furthermore, because of using the adaptive type active control, the noise silencing effect

can be exhibited all the time also on the variation of the combustion noise.

In order to achieve the second object of the present invention, a second mode of the apparatus of the present invention comprises: a pressure detector for detecting pressure variations caused by the combustion, thereby to cancel the pressure variation by phase interference by means of feedforward type control wherein an anti-phase signal is produced based on a signal from the pressure detector to issue an anti-phase sound; the combustion apparatus further comprising: a first pressure detector for detecting the pressure variation caused by the combustion in a combustion chamber; acoustic wave generation means for generating the anti-phase sound provided at upper side of the exhaust outlet; a second pressure detector provided between and in proximity to the exhaust outlet and the acoustic wave generation means; pressure propagation characteristic correction means for correcting an influence of a pressure propagation characteristics for a range from the acoustic wave generation means to the second pressure detector; adaptive processing means for computing based on the adaptive control rule an anti-phase signal which makes combustion noise cancel by the phase interference in accordance with the signal of the first pressure detector and the signal of the second pressure detector having passed through the electric filter for correcting a change of pressure propagation characteristic, and thereby to minimize signals to be detected by the second pressure detector; and means for radiating output signal of the adaptive processing device as acoustic wave from the acoustic wave generation means.

In accordance with the above constitution, the electric filter for correcting a change of pressure propagation characteristic corrects the pressure propagation characteristic i.e., the acoustic wave propagation characteristics for a range from the acoustic wave generation means to the pressure detector and the electro-acoustic conversion characteristic. Then the acoustic wave generation means generates the anti-phase sound with a sufficient accuracy. Since the acoustic wave generation means is provided in the vicinity of the exhaust outlet, constitution becomes a positive-negative doublet sound source. Thereby the combustion noise of low frequencies radiated from the exhaust outlet can be reduced for all the directions. And, in case that, for the combustion noise, the Helmholtz resonance determined by the space of such as the combustion chamber and the exhaust duct is dominant, and the combustion noise can be reduced even when the distance between the first pressure detector and the acoustic wave generation means is made as short as less than 60 cm.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG.1 is a front view of a gas hot water server as a first working example of the combustion apparatus of the present invention.

FIG.2 is an expanded cross-sectional view of a gas flow rate controlling valve with related circuit of the above-mentioned example.

FIG.3 is a circuit diagram inside a signal processing means of the above-mentioned example.

FIG.4 is a schematic drawing of internal constitution of the above-mentioned apparatus.

FIG.5(a), FIG.5(b) and FIG.5(c) are graphs of waveforms of pressure levels showing principle of noise silencing of the above-mentioned example.

FIG.6 is a cross-sectional view of installation of a microphone of the above-mentioned example.

FIG.7 is a front view of a gas hot water server as a second working example of the combustion apparatus of the present invention.

FIG.8 is a circuit diagram inside a signal processing means of the above-mentioned example.

FIG.9 is a front view of a gas hot water server as a third working example of the combustion apparatus of the present invention.

FIG.10 is a circuit diagram inside a signal processing means of the above-mentioned example.

FIG.11 is a front view of a gas hot water server as a fourth working example of the combustion apparatus of the present invention.

FIG.12 is a cross-sectional view of installation of a speaker of the above-mentioned example.

FIG.13 is a noise silencing characteristic of the above-mentioned example.

FIG.14 is a front view of a gas hot water server as a fifth working example of the combustion apparatus of the present invention.

FIG.15 is a radiation pattern of a positive-negative doublet sound source of the above-mentioned example.

FIG.16 is a front view of a gas hot water server as a sixth working example of the combustion apparatus of the present invention.

FIG.17 is a front view of a gas hot water server as a seventh working example of the combustion apparatus of the present invention.

FIG.18 is a front sectional view of a heat exchanger of the examples of the present invention.

FIG.19 is a front view of a gas hot water server as a eighth working example of the combustion apparatus of the present invention.

FIG.20 is a radiation pattern of a negative-positive-negative triplet sound source of the above-mentioned example.

FIG.21 is a schematic drawing of a combustion apparatus of the first prior art wherein an active control is applied to.

FIG.22(a), FIG.22(b) and FIG.22(c) are waveforms of pressure levels and noise silencing of the above-mentioned first prior art apparatus.

FIG.23 is a schematic partial section view of a combustion apparatus of a second prior art wherein an active control is applied to.

FIG.24 is a schematic drawing of an electronic si-

lencing system of a third prior art wherein an active control is applied to.

FIG. 25 is a block diagram showing a model of the above-mentioned third prior art.

It will be recognized that some or all of the Figures are schematic representations for purposes of illustration and do not necessarily depict the actual relative sizes or locations of the elements shown.

DESCRIPTION OF THE PREFERRED EMBODIMENT

«(FIRST EMBODIMENT)»

In the following, a first working example of the present invention is explained in a case embodied in a small size gas hot-water server for home use shown in FIG. 1 to FIG. 6.

The constitution of the present working example, as shown in FIG. 1 and FIG. 2, comprises in a casing 15: a sirocco fan 9 which is a blower for supplying air for the combustion, a gas flow control valve 10 which is a fuel control means for controlling the flow rate of gas used as a fuel, a main body controller 11 for supplying a combustion rate control signal to the gas flow control valve 10 and the sirocco fan 9. The main body controller controls these for controlling the temperature of served water from the hot water server. The apparatus further comprises a valve controller 12 for controlling the gas flow control valve 10, a mixing chamber 13 for mixing gas and air appropriately, an exhaust duct 16 having an exhaust outlet 17, and a heat exchanger for transferring the heat by the combustion to water. And further the apparatus comprises a microphone 19 which is a pressure detector provided in the combustion chamber 14 for taking out the pressure variation occurring in the combustion, a signal processing device 20 which is an adaptive signal processing means for computing signals substantially becoming anti-phase based on the signal detected by the microphone 19, a DC voltage controller 21 (FIG. 2) for feeding a DC voltage to the valve controller 12 which controls the gas flow rate by driving the gas flow control valve 10, and a DC/AC mixing circuit 22 for superimposing an AC voltage on the above-mentioned DC voltage.

Hereupon, the gas flow control valve 10 is, as shown in FIG. 2, of a moving coil type, which is superior in quick response characteristic because of its lightweight driven element. It comprises a gas inlet port 23, a valve seat 25, a valve body 26, a spring 27 for pushing up the valve body 26, a magnet 28 and a coil 29 for pushing down the valve body 26, and a shaft 30 for connecting the coil 29 and a valve body 26. Furthermore, the above-mentioned signal processing device 20 comprises as shown in FIG. 3, a first amplifier 31 for amplifying a signal from the microphone 19, an A/D converter 32 for converting an analog signal to a digital signal, a fixed filter 33-1 which is a pressure propagation characteristic correction device composed of an FIR (Finite Impulse

Response) filter for filtering one of three signals divided from the signal from the A/D converter 32, an adaptive processing device 34 for computing the anti-phase signal based on the signal passed through the above-mentioned fixed filter 33-1 and other remaining two signals of those three signals, a D/A converter 35 for converting the anti-phase digital signal obtained above into an analog signal, and a second amplifier 36 amplifying signal from the D/A converter 35. The adaptive processing device 34 further comprises an adaptive filter 37 which is realized by an FIR filter whose coefficients are changeable and a coefficient updating circuit 38 whereby the coefficients of the adaptive filter 37 are updated and also whereinto a least-mean-square algorithm is installed.

In accordance with the constitution described above, the action and the effect described below are exhibited. First, explanation is given on an operation in which an anti-phase signal is applied on combustible gas as the pressure variation. The anti-phase signal computed by the signal processing device 20 is inputted to the DC/AC mixing circuit 22 of the valve controller 12 and outputted into the gas flow through the gas flow control valve 10, as the pressure variation. Hereupon, in accordance with the instruction of the main body controller 11, the gas flow control valve 10 controls the combustion rate in a manner to keep the gas flow rate constant. This is achieved by balancing between an upward force acted from the spring 27 and a pushing down force of the valve body 26 by a force given through the shaft 30 caused by the action of an electromagnetic force induced by the magnet 28 and the coil 29, depending on a DC voltage supplied from the DC voltage controller 21. Thereby the gap between the valve seat 25 and the valve body 26 is kept to a constant spacing. Under the state of keeping the constant spacing, by such action that the corrected anti-phase signal which has been mixed in the DC/AC mixing circuit 22 is inputted in the coil 29, the valve body 26 makes vibration by the action of the electromagnetic force. Thereby the spacing between the valve seat 25 and the valve body 26 also vibrates, and a pressure variation is superimposed on the gas. Next, explanation is given on the action and the effect of computation of the anti-phase signal and the suppression of the combustion noise. The fixed filter 33-1 is such one that has been made by identifying the pressure propagation characteristic C from the gas flow control valve 10 to the microphone 19 under the state where the gas hot water server is already being operated and the combustion is being made as shown in FIG. 4. Therefore, this pressure propagation characteristic C (in FIG. 3) includes such as an electrical signal to pressure variation conversion characteristic of the gas flow control valve 10, a sound pressure variation to electrical signal conversion characteristic of the microphone 19, a resonance characteristic occurring during the pressure propagation from the gas flow control valve 10 to the microphone 19, and variations of phase and amplitude characteristic occurring at the time when the pressure variation passes through

a flame.

Next, from the signal of the pressure variation in the combustion chamber 14 detected by the microphone 19, an influence of the pressure propagation characteristic C at the time of combustion is corrected by the fixed filter 33-1; and based on this signal, a corrected anti-phase signal is computed by the adaptive processing device 34. Thus a corrected anti-phase output waveform shown by a solid line of FIG.5(b) can be computed. Signal shown by this solid line of FIG.5(b) is outputted to the gas flow control valve 10, thereby producing a pressure variation in the fuel, and the output waveform of the pressure propagation characteristic C shown by FIG.5(a) which has been used for correction is superimposed when the above-mentioned pressure variation propagates down to the combustion chamber. As a result, such pressure variation waveform as shown by the solid line of FIG.5(c) (that which is obtainable by inverting the phase of the pressure waveform detected in the combustion chamber 14 shown by the dotted line) can effectively be realized in the combustion chamber 14. That is, since the pressure variation substantially becoming anti-phase to that occurring in the combustion chamber 14 can be realized with a sufficient accuracy in the combustion chamber 14, the pressure variation can be suppressed by the phase interference, thereby the combustion noise can be reduced largely.

Moreover, in the adaptive processing device 34, the coefficients of the adaptive filter 37 are updated by the least-mean-square algorithm of the coefficient updating circuit 38 in a manner that the combustion noise detected by the microphone 19 becomes minimum, and thus the corrected anti-phase signal is computed in real time. Therefore, even when the combustion level is changed and hence the combustion noise characteristic varies, the silencing effect can act regardless of the combustion state. And further, since the gas flow control valve 10 is used as a control actuator, control of the combustion rate and the suppression of the combustion noise can be achieved by a single valve. Moreover, for the anomalous combustion in which a large amount of NO_x and/or CO are produced in the exhaust gas and the combustion noise is large, when the microphone 19 detects a sound pressure exceeding a predetermined threshold, it is judged that an anomalous combustion takes place, and production of NO_x and/or CO can be suppressed by controlling the gas flow. That is, by the instruction of a main body controller 11, the voltage applied to the DC voltage controller 21 of a valve controller 12 is changed and the fuel flow rate is controlled. Thereby, the rotation speed of the sirocco fan 9 is controlled and the air supply rate can be controlled. And thus the occurrence of the anomalous combustion is prevented, and suppressing the yield of NO_x also becomes possible. And, as is shown in FIG.6, a microphone 19 has a constitution that a pressure intake tap 39 is attached to the combustion chamber 14, and this pressure intake tap 39 and the microphone 19 are connected by a silicon tube 41 in which

glass wool 40 is filled. By this configuration, in comparison with a constitution that the microphone 19 is attached directly to the combustion chamber 14, it is possible to reduce the characteristic degradation of the microphone 19 due to heat from 14. And, possible adverse effect to the acoustic transfer characteristic of standing-wave resonance occurring inside the silicon tube 14 is also reduced by the sound absorbing property of the glass wool 40.

Apart from the afore-mentioned example in which the least-mean-square method was used as for the method for making the detected signal energy minimum was taken up, the maximum likelihood estimate method, or other estimate methods can exhibit the similar effect. Furthermore, since those signals detected in the combustion chamber 14, in the mixing chamber 13, and in the exhaust duct 16 have mutually high correlations, a configuration that the microphone 19 is provided in the mixing chamber 13 or in the exhaust duct 16 also exhibits the similar effect. Moreover, apart from the above-mentioned configuration of using the microphone 19 as the pressure detector, other detectors can be used for detecting other physical variations caused by the fire flame of the combustion such as a vibration detector for detecting the vibration associated with the fire flame on the outer wall, in the combustion chamber 14, or an optical detector for detecting the light radiated from the fire flame, or an ion current detector for detecting an ion current flowing corresponding to the chemical reaction of the combustion, also exhibiting the similar effect.

《(SECOND EMBODIMENT)》

Next, the second working example of the present invention is explained referring to FIG. 7 and FIG.8. To those parts having the same construction and performing the same function as in the first working example described above, the same numerals are given and detailed explanations on those parts are omitted, and the explanation is given mainly on the parts differing from the first working example.

As is shown in FIG.7 and FIG.8, the constitution of the present working example comprises: a first microphone 19a provided in a combustion chamber 14, a second microphone 19b provided at the upper part of an exhaust outlet 17, a first amplifier 31a for amplifying the signal detected by the first microphone 19a, a first A/D converter 32a for converting this signal to a digital signal, a second amplifier 31-b for amplifying the signal detected by the second microphone 19b, a second A/D converter 32b for converting this signal to a digital signal, a fixed filter 33-2 for issuing the anti-phase signal, an adaptive processing device 34 having therein an adaptive filter 37, and a coefficient updating circuit 38 for updating the coefficient. The fixed filter 33-2 for realizing the pressure propagation characteristic at the time of combustion is the one which is resulted by identifying the pressure propagation characteristic D of,

such as, electrical signal to pressure variation conversion characteristic of the gas flow control valve 10, a sound pressure variation to electrical signal conversion characteristic of the microphone 19b, a resonance characteristic occurring during the pressure propagation for a range from the gas flow control valve 10 to the microphone 19b, and variations of pressure variation characteristic occurring at the time when the pressure variation passes through the flame.

In accordance with the above-mentioned constitution, pressure variation occurring in the combustion chamber 14 is detected by the first microphone 19a, and the combustion noise radiated from an exhaust outlet 17 is detected by the second microphone 19b provided at the upper part of the exhaust outlet 17. The signal detected by the first microphone 19a passes through the first amplifier 31a and the first A/D converter 32a and divided into two. One signal is taken into the fixed filter 33-2, other signal is taken into the adaptive filter 37. At the coefficient updating circuit 38, signal passed through the fixed filter 33-2 and signal detected by the second microphone 19b are taken into it. The coefficient updating circuit 38 installs therein a least-mean-square algorithm by which the squared values of errors of signal detected by the second microphone 19b become minimum, and therein the coefficients of the adaptive filter 37 are updated in a manner that the phase characteristic of the signal detected by the first microphone 19a is inverted. The signal detected by the first microphone 19a is inputted into the fixed filter 33-2, in which the pressure propagation characteristic is realized and a digital anti-phase signal of corrected anti-phase characteristic is issued from the adaptive processing device 34. This corrected anti-phase signal is outputted to the combustible gas as a pressure variation. On the corrected anti-phase pressure variation impressed on gas, the effect of pressure propagation characteristic is further superimposed during the propagation process down to the combustion chamber 14, thus it becomes effectively anti-phase in the combustion chamber, and the pressure variation is suppressed by the phase interference. The adaptive processing device 34 performs the control in a manner that the sound pressure impressed on the second microphone 19b detected at the exhaust outlet 17 becomes minimum at the exhaust outlet 17, from which most of the combustion noise is radiated, and therefore the combustion noise can be suppressed certainly.

«(THIRD EMBODIMENT)»

Next, a third working example of the present invention is explained referring to FIG. 9 and FIG. 10. To those parts having the same construction and performing the same function as in the first working example described earlier, the same numerals are given and detailed explanations on those parts are omitted. And the explanation is given mainly on the parts differing from the first working example.

As is shown in FIG. 9 and FIG. 10, the constitution of the present working example comprises: a first microphone 19a provided in a combustion chamber 14, a second microphone 19b provided at the upper part of an exhaust outlet 17, a mixing chamber 13 for mixing fuel air and located at upper stream side of the flame, a speaker 42 which is an acoustic wave generation means, a first amplifier 31a for amplifying the signal detected by the first microphone 19a, a first A/D converter 32a for converting this signal to a digital signal, a second amplifier 31b for amplifying the signal detected by the second microphone 19b, a second A/D converter 32b for converting this signal to a digital signal, a fixed filter 33-3 for issuing the anti-phase signal, an adaptive processing device 34 for issuing an anti-phase signal, an adaptive filter 37 provided in the adaptive processing device 34 and a coefficient updating circuit 38. The fixed filter 33-3 identifies and realizes the acoustic transfer characteristic E from the speaker 42 to the second microphone 19b.

In accordance with the above-mentioned constitution, the pressure variation occurring in the combustion chamber 14 is detected by the first microphone 19a, the combustion noise radiated from the exhaust outlet 17 is detected by the second microphone 19b provided at the upper part of 17. The signal detected by the first microphone 19a passes through the first amplifier 31a and the first A/D converter 32a and divided into two. One signal is taken into the fixed filter 33-3, other signal is taken into the adaptive filter 37. The fixed filter 33-3 is composed of an FIR filter realizing an acoustic transfer characteristic E at the time of combustion from the speaker 42 down to the second microphone 19b. At the coefficient updating circuit 38, signal passed through the fixed filter 33-3 and signal detected by the second microphone 19b are taken into it. Since the coefficient updating circuit 38 installs a least-mean-square algorithm, which is the adaptive control rule whereby the squared values of errors of signal detected by the second microphone 19b become minimum, the coefficients of the adaptive filter 37 are updated in a manner that the phase characteristic of the signal detected by the first microphone 19a is inverted.

At the adaptive processing device 34, signal detected by the first microphone 19a is inputted into the adaptive filter 37 which is for realizing the anti-phase characteristic, and a digital anti-phase signal of corrected anti-phase characteristic is issued. This corrected anti-phase signal is converted into analog signal by the D/A converter 35, amplified by the second amplifier 36 and inputted into the speaker 42. Then, the speaker 42 outputs a pressure variation, which is of corrected anti-phase to the sound generated from the flame vibration, is outputted into the gas-air mixed gas. The pressure variation of the corrected anti-phase superimposed on the mixed gas propagates down to the combustion chamber 14, and the pressure variation is suppressed by the phase interference.

Furthermore, since the adaptive processing device 34 performs the control in a manner to minimize the sound pressure impressed on the second microphone 19b detected at the exhaust outlet 17 by driving the speaker 42, the suppression of the combustion noise can be made certainly at the exhaust outlet 17, from which most of the combustion noise is radiated. Hereupon, by installing a speaker 42 in the mixing chamber 13, it becomes possible to apply the anti phase sound over the whole volume of gas for the combustion. Thereby, as compared with a prior art constitution in which the anti-phase sound is applied only on fuel and air, the combustion noise can be suppressed more efficiently. Moreover, since the noise detected by the first microphone 19a includes not only combustion noise but also blower noise generated by the sirocco fan 9, the speaker 42 can also silence the blower noise.

A further example comprises: A feed back circuit including a pressure detector 19 generating an electric signal in response to pressure variations substantially being caused by the combustion and signal processing means (20) producing an anti-phase signal based on the signal from said pressure detector and applied to an acoustic wave generation means (42) to cancel said pressure variations by phase interference wherein said acoustic wave generation means (42) is provided in a mixing chamber 13 in which fuel and air are mixed at the upper stream side of a burner to generate an anti-phase sound corresponding to said anti-phase signal; the signal processing means (20) including a fixed electric filter (33-3) correcting an acoustic transfer characteristic of a range from said acoustic wave generation means to said pressure detector (19) under the state of combustion, said acoustic transfer characteristic having been identified beforehand under the state of combustion; and adaptive processing means (34) computing the anti-phase signal; said adaptive processing means (34) including an adaptive filter (37) operating in response to the output of said fixed electric filter (33-3) via a filter coefficient updating circuit (38) as well as the signal from the pressure detector directly, said filter coefficient updating circuit (38) updating the coefficients of the adaptive filter; and means for applying the anti-phase signal of said adaptive filter processing means to said acoustic wave generation means (42).

(Fourth embodiment)

Next, the fourth working example of the present invention is explained referring to FIG. 11 and FIG. 12. To those parts having the same construction and performing the same function as in the first working example, described earlier, the same numerals are given and detailed explanations on those parts are omitted. And the explanation is given mainly on the parts differing from the first working example.

As is shown in FIG. 11 and FIG. 12, the constitution of the present working example comprises: a first micro-

phone 19a provided in a combustion chamber 14, a second microphone 19b provided at the upper part of an exhaust outlet 17, and a speaker 42 provided in the exhaust duct at the down stream side of the flame as an acoustic wave generation means for generating acoustic wave of an anti-phase into an exhaust duct 16. At this time, the distance between the first microphone 19a and the speaker 42 is as short as less than several 10 cm. And, the fixed filter 33-3 (shown in FIG. 10) identifies and realizes the acoustic transfer characteristic F on which the acoustic output from the speaker 42 propagates down to the second microphone 19b. Furthermore, it is constituted by covering the speaker 42 with a speaker box 43, and, by providing a heat-resistive thin vibration plate 44 between the exhaust duct 16 and the speaker 42 at the same time.

In accordance with the above-mentioned constitution, signal detected by the first microphone 19a is, as is shown in FIG. 10, divided into two. One signal is taken into the fixed filter 33-3, and the other signal is taken into the adaptive filter 37. The fixed filter 33-3 is composed of an FIR filter for realizing an acoustic transfer characteristic F at the time of combustion for a range from the speaker 42 down to the second microphone 19b. Signal detected by the first microphone 19a is inputted into the adaptive filter 37, and a digital anti-phase signal of inverted characteristic is issued therefrom. This corrected anti-phase signal is converted into analog signal by the D/A converter 35, after amplified by the second amplifier 36, inputted into the speaker 42, and then, sound of corrected anti-phase to what is generated from the flame vibration is generated from the speaker 42. At this time, the acoustic wave makes the thin vibrating plate 44 vibrate, thus to issue the acoustic wave from the thin vibrating plate 44 into the exhaust gas in the exhaust duct 16. The sound substantially becoming anti-phase is generated from the speaker 42 when the combustion noise generated due to the fire flame propagates in the exhaust duct 16, and thereby the combustion noise is canceled by the phase interference action. That is, a feedforward control acts on the speaker 42 in a manner to minimize the sound pressure impressed on the second microphone 19b detected at the exhaust outlet 17, and the combustion noise radiated from the exhaust outlet 17 can be suppressed as is shown in FIG. 13.

Hereupon, in a system in which periodic noises are removed and a control system based on the ANC (Active Noise Control) is applied, it is said that, at least several msec is necessary for the time period which starts from the detection of noise, performs the computation of the anti-phase based on the detected signal and finishes the issuing of the sound from the speaker 42. That is, in order to silence the noise detected by the first microphone 19a by the speaker 42, more than 1 meter is required for the distance between the first microphone 19a and the speaker 42. However, the inventor found by experiment that the silencing of noise was possible

by a distance less than 60 cm. The reason is estimated that, for the combustion noise occurring in small size gas hot water servers or the likes, fluctuating sound generated by the Helmholtz resonance determined by the volume of the mixing chamber 13 and the combustion chamber 14 as well as by the length of the exhaust duct 16 is dominant. Even during the time which is not sufficient to cover the computation time (about 1 msec), for the noise whose main components are the resonating sound of low frequency range, the noise silencing effect can be exhibited by predicting the succeeding variation, hence it makes the noise silencing possible with a short distance less than several ten cm. Hereupon, when the Helmholtz resonance occurs, particle velocity takes its maximum value at such part of the exhaust duct 16 that the cross-sectional area of the duct is smallest. Since the speaker 42 is provided in the exhaust duct, the acoustic impedance can be changed by controlling the particle velocity by driving the speaker 42, and thus the resonance sound can be reduced.

«(FIFTH EMBODIMENT)»

Next, the fifth working example of the present invention is explained referring to FIG. 14. To those parts having the same construction and performing the same function as those in the fourth working example described above, the same numerals are given and detailed explanations on those parts are omitted. And the explanation is given mainly on the parts differing from the fourth working example.

As is shown in FIG.14, the constitution of the present working example comprises: a first microphone 19a provided in a combustion chamber 14, a speaker 42 provided on the upper side of an exhaust outlet 17 as an acoustic wave generation means for generating sound of an anti-phase, a second microphone 19b provided at a center on a line connecting the center of the speaker 42 and the center of the exhaust outlet 17, a first amplifier 31a (FIG.10) for amplifying the signal detected by a first microphone 19a, a first A/D converter 32a for converting this signal to a digital signal, a second amplifier 31b for amplifying the signal detected by the second microphone 19b, a second A/D converter 32b for converting this signal to a digital signal, an adaptive processing device 34 including an adaptive filter 37 therein for issuing an anti-phase signal, a fixed filter 33-3, and a coefficient updating circuit 38. The fixed filter 33-3 identifies and realizes the acoustic transfer characteristic G for the sound path for a range from the speaker 42 to the second microphone 19b. At this time, the distance between the first microphone 19a and the speaker 42 is as short as less than 60 cm.

In accordance with the above-mentioned constitution, the pressure variation occurring in the combustion chamber 14 is detected by the first microphone 19a, the combustion noise radiated from the exhaust outlet 17 is detected by the second microphone 19b provided at the

upper part of the exhaust outlet 17. The signal detected by the first microphone 19a passes through the first amplifier 31a and the first A/D converter 32a and divided into two. One signal is taken into the fixed filter 33-3, and the other signal is taken into the adaptive filter 37. The fixed filter 33-3 is composed of an FIR filter realizing an acoustic transfer characteristic G for a range from the speaker 42 down to the second microphone 19b. At the coefficient updating circuit 38, signal passed through the fixed filter 33-3 and signal detected by the second microphone 19b are taken into it. And a least-mean-square algorithm, which is the adaptive control rule, by which the squared values of errors of signal detected by the second microphone 19b become minimum is installed in the coefficient updating circuit 38. Therefore the coefficients of the adaptive filter 37 are updated in a manner that the phase characteristic of the signal detected by the first microphone 19a is inverted. Into the adaptive filter 37 in which the corrected inverted characteristic is realized, the signal detected by the first microphone 19a is inputted, and digital anti-phase signal of corrected inverted characteristic is outputted. This corrected anti-phase signal is converted into analog signal by the D/A converter 35, and then amplified by the second amplifier 36. Then, the amplified signal is inputted into the speaker 42 provided at the upper part of the exhaust outlet 17, and thus from the speaker 42 a corrected acoustic wave substantially becoming in anti-phase is issued.

Hereupon, the combustion noise is a low-frequency noise of long wavelength, and almost thereof is radiated from the exhaust outlet 17 into space. Now, the exhaust outlet 17 is taken as a positive sound source and the speaker 42 as a negative sound source is provided at a sufficiently short distance therefrom in comparison with this wavelength, and further the sound radiation planes of the exhaust outlet 17 and the speaker 42 are arranged on one common plane, and the second microphone 19b is provided at a nearest position to this radiation plane and on a line connecting centers thereof; then, a positive-negative doublet sound source can be realized. That is, as is shown in FIG.15, which is the radiation pattern of noise silencing action, the combustion noise in the front direction can be reduced largely, exhibiting a characteristic enabling the reduction of the combustion noise in all the directions, upper-, lower-, left-, and right-directions.

«(SIXTH EMBODIMENT)»

Next, on the sixth working example of the present invention, explanation is given referring to FIG. 16. To those parts having the same construction and performing the same function as in the fifth working example described above, the same numerals are given and detailed explanations on those parts are omitted; and the explanation is given mainly on the parts differing from the fifth working example.

As is shown in FIG.16, the constitution of the present working example is that in which a first microphone 19a is provided in the mixing chamber 13 for mixing the gas and air therein.

By using the above constitution, the pressure variation of mixing chamber 13 is detected by the first microphone 19a, and the combustion noise radiated from the exhaust outlet 17 is detected by the second microphone 19b provided at the upper part of the exhaust outlet 17. The control action for performing the silencing of noise is carried out by the same function as in the above fifth working example. At this time, since the first microphone 19a is provided in the mixing chamber 13, the first microphone 19a does not suffer any adverse influence due to heat, thereby the degradation-resistant characteristic or the durability against heat is improved.

《SEVENTH EMBODIMENT》

Next, a seventh working example of the present invention is explained referring to FIG. 17 and FIG.18. To those parts having the same construction and performing the same function as in the fifth working example described before, the same numerals are given and detailed explanations on those parts are omitted; and the explanation is given mainly on the parts differing from the fifth working example.

As is shown in FIG.17, the constitution of the present working example is provided with an exhaust duct 16 for conducting heat and the exhaust gas produced by the combustion to an exhaust outlet 17, a heat exchanger 18 provided in the exhaust duct 16, and its first microphone 19a is set between the heat exchanger 18 and the exhaust outlet 17.

By using the above constitution, as is shown in FIG. 18, the first microphone 19a detects combustion noise of combustion-generated exhaust gas, after its turbulent flow is rectified by making it pass through spaces between a plurality of heat-collecting plates 45 of a heat exchanger 18, and the second microphone 19b (in FIG. 17) detects the combustion noise radiated from the exhaust outlet 17. The control action for performing the silencing of noise is to be carried out by the same function as in the fifth working example described before. At this time, since the first microphone 19a is provided between the heat exchanger 18 and the exhaust outlet 17, the first microphone 19a detects the combustion noise after the turbulent noise caused by the turbulence of the flow is suppressed by the rectification effect of a plurality of heat-collecting plates 45. Accordingly, the combustion noise in which the turbulent noise was subtracted from the combustion sound can be detected, and this makes a high-fidelity realization of the corrected anti-phase sound possible; and thereby an improvement of the suppression effect on the combustion noise by the phase interference becomes possible.

《EIGHTH EMBODIMENT》

Next, an eighth working example of the present invention is explained referring to FIG. 19 and FIG.20. To those parts having the same construction and performing the same function as in the fifth working example described before, the same numerals are given, and detailed explanations on those parts are omitted. And the explanation is given mainly on the parts differing from the first working example.

As is shown in FIG.19, two speakers 42 are provided for making the noise silencing at two positions of both of left and right sides, and corrected anti-phase signal is divided and outputted. And, between respective speakers 42 and the exhaust outlet 17, two of the second microphone 19b are provided respectively. Then, two signals obtained from these respective microphones are added and taken into the signal processing means 20.

By using the above constitution, the combustion noise radiated into space from the exhaust outlet 17 is detected by two second microphones 19b. Since a corrected anti-phase sounds from those two speakers 42 are radiated in a manner that the detected combustion noise becomes minimum, the sound source constitution becomes a negative-positive-negative triplet. Thereby, the combustion noise of a radiation pattern shown in FIG.20 can be exhibited.

Moreover, apart from the present working example wherein two speakers 42 were placed at two positions on left- and right-hand sides, a modified constitution may be configured such as placing them on upper and lower sides, which also can exhibit the similar effect.

Claims

1. A combustion apparatus comprising fuel supply control means (10,12) controlling the amount of fuel supplied to a burner to be combusted and a feed back circuit including a pressure detector (19) generating an electric signal in response to pressure variations substantially being caused by the combustion and signal processing means (20) producing an anti-phase signal based on the signal from said pressure detector and applied to said fuel supply control means (10,12) to cancel said pressure variations by phase interference, **characterized in that**

said fuel supply control means include a gas flow control valve (10) operating under action of a valve controller (12) for controlling a flow rate of gas to be supplied to the burner, said valve controller (12) having a DC voltage controller (21) feeding a DC voltage to said control valve (10) and a DC/AC mixing circuit (22) superimposing on said DC voltage an AC volt-

age corresponding to the anti-phase signal,
and

the signal processing means (20) including a
fixed electric filter (33-1) correcting a pressure
propagation characteristic of a range from said
control valve to said pressure detector (19) under
the state of combustion, said pressure
propagation characteristic having been identified
beforehand under the state of combustion;
and

adaptive processing means (34) for computing
the anti-phase signal;

said adaptive processing means (34) including
an adaptive filter (37) operating in response to
the output of said fixed electric filter (33-1) via
a filter coefficient updating circuit (38) as well
as the signal from the pressure detector directly,
said filter coefficient updating circuit (38) updating
the coefficients of the adaptive filter; and
means for applying the anti-phase signal of said
adaptive filter processing means to said valve
controller.

2. A combustion apparatus in accordance with claim
1, wherein
the signal from the pressure detector (19) is supplied
to the coefficient updating circuit (38) for updating
the coefficients of the adaptive filter.

3. A combustion apparatus in accordance with claim
1, wherein
the signal from a second pressure detector (19b)
detecting the pressure variations at the combustion
apparatus exhaust outlet is supplied to the coefficient
updating circuit (38) for updating the coefficients
of the adaptive filter (37).

4. A combustion apparatus in accordance with claim
1, characterized in that:

the pressure detector (19a) is arranged in a
combustion chamber;

a further pressure detector (19b) is arranged at
an exhaust outlet;

said fixed electric filter (33-2) is adapted to correct
the pressure propagation characteristic of a range
from said control valve (10) to said further pressure
detector (19b), said pressure propagation characteristic
having been identified beforehand under the state of
combustion; and the signal from the further pressure
detector (19b) is supplied to the coefficient updating
circuit (38) for updating the coefficients of the
adaptive filter (37).

5. A combustion apparatus in accordance with claim
1 in which the pressure detector (19) is placed in a
tube (41) of a pressure intake tap (39) opening to

the combustion chamber (14), said tube holding an
acoustic damper (40).

6. A combustion apparatus wherein fuel and air are
supplied to a burner, said apparatus comprising a
feed back circuit including a pressure detector (19)
generating an electric signal in response to pressure
variations substantially being caused by the
combustion and signal processing means (20) producing
an anti-phase signal based on the signal from said
pressure detector and applied to an acoustic wave
generation means (42) to cancel said pressure
variations by phase interference, characterized in that

said acoustic wave generation means (42) is
provided in a mixing chamber (13) in which fuel
and air are mixed at the upper stream side of a
burner to generate an anti-phase sound corresponding
to said anti-phase signal;

the signal processing means (20) including a
fixed electric filter (33-3) correcting an acoustic
transfer characteristic of a range from said
acoustic wave generation means to said pressure
detector (19) under the state of combustion, said
acoustic transfer characteristic having been identified
beforehand under the state of combustion; and

adaptive processing means (34) computing the
anti-phase signal;

said adaptive processing means (34) including
an adaptive filter (37) operating in response to
the output of said fixed electric filter (33-3) via
a filter coefficient updating circuit (38) as well
as the signal from the pressure detector directly,
said filter coefficient updating circuit (38) updating
the coefficients of the adaptive filter; and
means for applying the anti-phase signal of said
adaptive filter processing means to said acoustic
wave generation means (42).

7. A combustion apparatus wherein fuel and air are
supplied to a burner, said apparatus comprising a
feed-forward type control including a pressure
detector (19a) generating an electric signal in
response to pressure variations substantially being
caused by the combustion and signal processing
means (20) producing an anti-phase signal based
on the signal from said pressure detector and applied
to an acoustic wave generation means (42) to cancel
said pressure variations by phase interference, characterized in that

said acoustic wave generation means (42) for
generating the anti-phase sound is provided at
the upper side of an exhaust outlet (17);
the pressure detector (19a) is arranged in a
combustion chamber;

a further pressure detector (19b) is provided between and in proximity to the exhaust outlet (17) and said acoustic wave generation means (42);

the signal processing means (20) including a fixed electric filter (33-3) correcting an acoustic transfer characteristic of a range from said acoustic wave generation means to said second pressure detector (19b) under the state of combustion, said acoustic transfer characteristic having been identified beforehand under the state of combustion; adaptive processing means (34) computing the anti-phase signal; said adaptive processing means (34) including an adaptive filter (37) operating in response to the output of said fixed electric filter (33-3) via a filter coefficient updating circuit (38) as well as the signal from the pressure detector directly, and said filter coefficient updating circuit (38) updating the coefficients of the adaptive filter (37).

8. A combustion apparatus wherein fuel and air are supplied to a burner, said apparatus comprising a feed-forward type control including a pressure detector (19a) generating an electric signal in response to pressure variations substantially being caused by the combustion and signal processing means (20) producing an anti-phase signal based on the signal from said pressure detector and applied to an acoustic wave generation means (42) to cancel said pressure variations by phase interference, **characterized in that**

a mixing chamber is arranged in which fuel and air are mixed;

said acoustic wave generation means (42) for generating the anti-phase sound is provided at the upper side of an exhaust outlet (17);

the pressure detector (19a) detects the pressure variation caused by the combustion either in the burner part (13) or an exhaust duct (16) for leading the exhaust gas of combustion to the exhaust outlet (17);

a further pressure detector (19b) is provided between and in proximity to the exhaust outlet (17) and said acoustic wave generation means (42);

the signal processing means (20) including a fixed electric filter (33-3) correcting an acoustic transfer characteristic of a range from said acoustic wave generation means to said second pressure detector (19b) under the state of combustion, said acoustic transfer characteristic having been identified beforehand under the state of combustion;

adaptive processing means (34) computing the

anti-phase signal;

said adaptive processing means (34) including an adaptive filter (37) operating in response to the output of said fixed electric filter (33-3) via a filter coefficient updating circuit (38) as well as the signal from the pressure detector directly, and

said filter coefficient updating circuit (38) updating the coefficients of the adaptive filter (37).

9. A combustion apparatus in accordance with one of claims 6 to 8 further comprising:

a plural number of acoustic wave generation means (42) provided at the edge of the exhaust outlet (17), and

a plural number of second pressure detectors (19b) provided respectively between said exhaust outlet (17) and said acoustic wave generation means (42).

Patentansprüche

1. Verbrennungsvorrichtung, die Kraftstoffversorgungs-Steuerungseinrichtungen (10, 12) umfaßt, die den Betrag des Kraftstoffes, der zu einem Brenner geliefert wird, um verbrannt zu werden, steuern, und eine Rückkopplungsschaltung umfaßt, die einen Druckdetektor (19) beinhaltet, welcher ein elektrisches Signal in Antwort auf die Druckveränderungen, welche im wesentlichen durch die Verbrennung verursacht werden, erzeugt, und Signalverarbeitungseinrichtungen (20) umfaßt, die ein Antiphasensignal basierend auf dem Signal von dem Druckdetektor herstellen und welches an die Kraftstoffversorgungs-Steuerungseinrichtungen (10, 12) geliefert wird, um die Druckveränderungen durch Phaseninterferenz auszulöschen, **dadurch gekennzeichnet, daß**

die Kraftstoffversorgungs-Steuerungseinrichtung ein Gasfluß-Steuerungsventil (10) beinhaltet, welches unter Wirkung einer Ventilsteuerungseinrichtung (12) zum Steuern einer Flußrate an Gas, welches an den Brenner zu liefern ist, funktioniert,

die Ventilsteuerungseinrichtung (12) eine Gleichspannungs-Steuerungseinrichtung (21), welche eine Gleichspannung in das Steuerungsventil (10) einspeist und eine Gleichspannungs/Wechselspannungs-Vermischungsschaltung (22) hat, die die Gleichspannung einer Wechselspannung korrespondierend zu dem Antiphasensignal überlagert, und die Signalverarbeitungseinrichtung (20) einen festgesetzten elektrischen Filter (33-1) beinhaltet, welcher eine Druckausbreitungsscha-

- rakteristik eines Bereiches von dem Steuerungsventil zu dem Druckdetektor (19) unter dem Verbrennungszustand korrigiert, wobei die Druckausbreitungscharakteristik vorher während des Verbrennungszustandes identifiziert worden ist; und
 5 anpassungsfähige Verarbeitungseinrichtungen (34) zum Berechnen des Antiphasensignales;
 10 die anpassungsfähige Verarbeitungseinrichtung (34) einen anpassungsfähigen Filter (37) beinhalten, welcher in Antwort auf den Ausgang des festgesetzten elektrischen Filters (33-1) über eine Filterkoeffizienten-Aktualisierungsschaltung (38) als auch dem Signal von dem Druckdetektor direkt funktioniert, wobei
 15 die Filterkoeffizienten-Aktualisierungsschaltung (38) die Koeffizienten des anpassungsfähigen Filters aktualisiert; und
 20 Einrichtungen zum Anwenden des Antiphasensignales von den anpassungsfähigen Filter-Verarbeitungseinrichtungen auf die Ventilsteuerungseinrichtung.
2. Verbrennungsvorrichtung nach Anspruch 1, worin
 25 das Signal von dem Druckdetektor (19) an die Koeffizienten-Aktualisierungsschaltung (38) zum Aktualisieren der Koeffizienten des anpassungsfähigen Filters geliefert wird.
3. Verbrennungsvorrichtung nach Anspruch 1, worin
 30 das Signal von einem zweiten Druckdetektor (19b), welcher die Druckveränderungen an dem Verbrennungsvorrichtungsausblasausgang detektiert, an die Koeffizienten-Aktualisierungsschaltung (38) zum Aktualisieren der Koeffizienten des anpassungsfähigen Filters (37) geliefert wird.
4. Verbrennungsvorrichtung nach Anspruch 1, **dadurch gekennzeichnet**, daß
 40 der Druckdetektor (19a) in einer Verbrennungskammer angeordnet ist; ein weiterer Druckdetektor (19b) in einem Ausblasausgang angeordnet ist; der festgesetzte elektrische Filter (33-2) dazu geeignet ist, die Druckausbreitungscharakteristik von einem Bereich von dem Steuerungsventil (10) zu dem weiteren Druckdetektor (19b) zu korrigieren, wobei die
 45 Druckausbreitungscharakteristik vorher während des Zustandes der Verbrennung identifiziert worden ist; und das Signal von dem weiteren Druckdetektor (19b) an die Koeffizienten-Aktualisierungsschaltung (38) zum Aktualisieren der Koeffizienten des anpassungsfähigen Filters (37) geliefert wird.
5. Verbrennungsvorrichtung nach Anspruch 1, in welcher der Druckdetektor (19) in einer Röhre (41) einer Druckansaugbohrung (39), die zu der Verbrennungskammer (14) geöffnet ist, plaziert ist, wobei

die Röhre einen akustischen Dämpfer (40) hält.

6. Verbrennungsvorrichtung, worin Kraftstoff und Luft an einen Brenner geliefert werden, wobei die Vorrichtung eine Rückkopplungsschaltung, welche einen Druckdetektor (19), der ein elektrisches Signal in Antwort auf die Druckveränderungen, die im wesentlichen durch die Verbrennung erzeugt werden, erzeugt, beinhaltet, und Signalverarbeitungseinrichtungen (20), die ein Antiphasensignal basierend auf dem Signal von dem Druckdetektor herstellen und welches auf eine akustische Wellenerzeugungseinrichtung (42) angewendet wird, um die Druckveränderungen durch Phaseninterferenz auszulöschen, umfaßt, **dadurch gekennzeichnet**, daß
- die akustische Wellenerzeugungseinrichtung (42) in einer Mischkammer (13) angeordnet ist, in welcher Kraftstoff und Luft in der oberen Stromseite eines Brenners vermischt werden, um einen Antiphasenklang korrespondierend zu dem Antiphasensignal zu erzeugen; die Signalverarbeitungseinrichtung (20) einen festgesetzten elektrischen Filter (33-3) beinhaltet, welcher eine akustische Übertragungscharakteristik eines Bereiches von der akustischen Wellenerzeugungseinrichtung zu dem Druckdetektor (19) während des Zustandes der Verbrennung korrigiert, wobei die akustische Übertragungscharakteristik vorher während des Zustandes der Verbrennung identifiziert worden ist; und
 anpassungsfähige Verarbeitungseinrichtung (34), die das Antiphasensignal berechnet; die anpassungsfähige Verarbeitungseinrichtung (34) einen anpassungsfähigen Filter (37) beinhalten, welcher in Antwort auf den Ausgang des festgesetzten elektrischen Filters (33-3) über eine Filterkoeffizienten-Aktualisierungsschaltung (38) als auch dem Signal von dem Druckdetektor direkt funktioniert, wobei die Filterkoeffizienten-Aktualisierungsschaltung (38) die Koeffizienten des anpassungsfähigen Filters aktualisiert; und
 Einrichtungen zum Anwenden des Antiphasensignals von der anpassungsfähigen Filter-Verarbeitungseinrichtung auf die akustische Wellenerzeugungseinrichtung (42).
7. Verbrennungsvorrichtung, worin Kraftstoff und Luft an einen Brenner geliefert werden, wobei die Vorrichtung eine Steuerung vom Typ der Optimalwertsteuerung umfaßt, welche einen Druckdetektor (19a) beinhaltet, der ein elektrisches Signal in Antwort auf die Druckveränderungen erzeugt, die im wesentlichen durch die Verbrennung erzeugt werden und die Signalverarbeitungseinrichtung (20)

umfaßt, welche ein Antiphasensignal basierend auf dem Signal von dem Druckdetektor herstellt und welches auf eine akustische Wellenerzeugungseinrichtung (42) angewendet wird, um die Druckveränderungen durch Phaseninterferenz auszulöschen, **dadurch gekennzeichnet, daß**

die akustische Wellenerzeugungseinrichtung (42) zum Erzeugen des Antiphasenklanges an der oberen Seite eines Ausblasausganges (17) geliefert wird;
 der Druckdetektor (19a) in einer Verbrennungskammer angeordnet ist; ein weiterer Druckdetektor (19b) zwischen und in unmittelbarer Nähe zu dem Ausblasausgang (17) und der akustischen Wellenerzeugungseinrichtung (42) angeordnet ist;
 die Signalverarbeitungseinrichtung (20) einen festgesetzten elektrischen Filter (33-3) beinhaltet, welcher eine akustische Übertragungscharakteristik eines Bereiches von der akustischen Wellenerzeugungseinrichtung zu dem zweiten Druckdetektor (19b) während des Zustandes der Verbrennung korrigiert, wobei die akustische Übertragungscharakteristik vorher während des Zustandes der Verbrennung identifiziert worden ist;
 anpassungsfähige Verarbeitungseinrichtungen (34), welche das Antiphasensignal berechnen;
 die anpassungsfähigen Verarbeitungseinrichtungen (34) einen anpassungsfähigen Filter (37) beinhalten, welcher in Antwort auf den Ausgang des festgesetzten elektrischen Filters (33-3) über eine Filterkoeffizienten-Aktualisierungsschaltung (38) als auch dem Signal von dem Druckdetektor direkt funktioniert, und die Filterkoeffizienten-Aktualisierungsschaltung (38) die Koeffizienten des anpassungsfähigen Filters (37) aktualisiert.

8. Verbrennungsvorrichtung, worin Kraftstoff und Luft an einen Brenner geliefert werden, wobei die Vorrichtung eine Steuerung vom Typ der Optimalwertsteuerung umfaßt, welche einen Druckdetektor (19a) beinhaltet, der ein elektrisches Signal in Antwort auf die Druckveränderungen erzeugt, die im wesentlichen durch die Verbrennung verursacht werden und Signalverarbeitungseinrichtungen (20) umfaßt, welche ein Antiphasensignal basierend auf dem Signal von dem Druckdetektor herstellt und welches an eine akustische Wellenerzeugungseinrichtung (42) zum Auslöschen der Druckveränderungen durch Phaseninterferenz geliefert wird, **dadurch gekennzeichnet, daß**

eine Mischkammer angeordnet ist, in welcher Kraftstoff und Luft vermischt werden;

die akustische Wellenerzeugungseinrichtung (42) zum Erzeugen des Antiphasenklanges in der oberen Seite eines Ausblasauslasses (17) angeordnet ist;
 der Druckdetektor (19a) die Druckveränderungen detektiert, welche durch die Verbrennung entweder in dem Brennteil (13) oder eine Ausblasrohrleitung (16) zum Führen der Ausblasgase von der Verbrennung zu dem Ausblasauslaß (17) verursacht werden;
 ein weiterer Druckdetektor (19b) zwischen und in unmittelbarer Nähe zu dem Ausblasauslaß (17) und der akustischen Wellenerzeugungseinrichtung (42) angeordnet ist;
 die Signalverarbeitungseinrichtung (20) einen festgesetzten elektrischen Filter (33-3) beinhaltet, welcher eine akustische Übertragungscharakteristik eines Bereiches von der akustischen Wellenerzeugungseinrichtung zu dem zweiten Druckdetektor (19b) während des Zustandes der Verbrennung korrigiert, wobei die akustische Übertragungscharakteristik vorher während des Zustandes der Verbrennung identifiziert worden ist;
 anpassungsfähige Verarbeitungseinrichtung (34), welche das Antiphasensignal berechnet;
 die anpassungsfähige Verarbeitungseinrichtung (34) beinhaltet einen anpassungsfähigen Filter (37), welcher in Antwort auf den Ausgang des festgesetzten elektrischen Filters (33-3) über eine Filterkoeffizienten-Aktualisierungsschaltung (38) als auch dem Signal von dem Druckdetektor direkt funktioniert, und die Filterkoeffizienten-Aktualisierungsschaltung (38) die Koeffizienten des anpassungsfähigen Filters (37) aktualisiert.

9. Verbrennungsvorrichtung nach einem der Ansprüche 6 bis 8, weiterhin umfassend:
 eine Vielzahl von akustischen Wellenerzeugungseinrichtungen (42), die an dem Rand des Ausblasauslasses (17) angeordnet sind, und eine Vielzahl von zweiten Druckdetektoren (19b), welche jeweils zwischen dem Ausblasauslaß (17) und der akustischen Wellenerzeugungseinrichtung (42) angeordnet sind.

Revendications

1. Appareil de combustion comprenant un moyen de commande d'alimentation en combustible (10, 12) commandant la quantité du combustible fourni à un brûleur pour être brûlé et un circuit de rétroaction comprenant un détecteur de pression (19) générant un signal électrique en réponse aux variations de pression qui sont principalement provoquées par la combustion et un moyen de traitement du signal

(20) produisant un signal en opposition de phase sur la base du signal provenant dudit détecteur de pression et appliqué audit moyen de commande d'alimentation en combustible (10, 12) afin d'annuler lesdites variations de pression grâce à l'interférence des phases, caractérisé en ce que

ledit moyen de commande d'alimentation en combustible comprend une soupape de commande de débit de gaz (10) fonctionnant sous l'action d'un contrôleur de soupape (12) destiné à commander un débit du gaz à fournir au brûleur,

ledit contrôleur de soupape (12) comportant un contrôleur de tension en courant continu (21) appliquant une tension en courant continu à ladite soupape de commande (10) et un circuit mélangeur courant continu/courant alternatif (22) superposant à ladite tension en courant continu une tension en courant alternatif correspondant au signal en opposition de phase, et

le moyen de traitement du signal (20) comprenant un filtre électrique fixe (33-1) qui corrige une caractéristique de propagation de pression sur une plage entre ladite soupape de commande et ledit détecteur de pression (19) dans un état de combustion, ladite caractéristique de propagation de pression ayant été identifiée à l'avance dans un état de combustion, et un moyen de traitement adaptatif (34) destiné à calculer le signal en opposition de phase, ledit moyen de traitement adaptatif (34) comprenant un filtre adaptatif (37) fonctionnant en réponse à la sortie dudit filtre électrique fixe (33-1) par l'intermédiaire d'un circuit de mise à jour de coefficients de filtre (38) de même qu'au signal provenant directement du détecteur de pression, ledit circuit de mise à jour de coefficients de filtre (38) mettant à jour les coefficients du filtre adaptatif, et

un moyen destiné à appliquer le signal en opposition de phase dudit moyen de traitement à filtre adaptatif audit contrôleur de soupape.

2. Appareil de combustion selon la revendication 1, dans lequel

le signal provenant du détecteur de pression (10) est appliqué au circuit de mise à jour de coefficients (38) destiné à mettre à jour les coefficients du filtre adaptatif.

3. Appareil de combustion selon la revendication 1, dans lequel

le signal provenant d'un second détecteur de pression (19b) qui détecte les variations de pression au niveau de l'orifice de sortie d'évacuation de l'appareil de combustion est appliqué au circuit de

mise à jour de coefficients (38) destiné à mettre à jour les coefficients du filtre adaptatif (37).

4. Appareil de combustion selon la revendication 1, caractérisé en ce que :

le détecteur de pression (19a) est agencé dans une chambre de combustion, un autre détecteur de pression (19b) est agencé dans un orifice d'évacuation, ledit filtre électrique fixe (33-2) est adapté pour corriger la caractéristique de propagation de pression sur une plage entre ladite soupape de commande (10) et ledit autre détecteur de pression (19b), ladite caractéristique de propagation de pression ayant été identifiée à l'avance dans un état de combustion, et le signal provenant de l'autre détecteur de pression (19b) est appliqué au circuit de mise à jour de coefficients (38) destiné à mettre à jour les coefficients du filtre adaptatif (37).

5. Appareil de combustion selon la revendication 1, dans lequel le détecteur de pression (19) est placé dans un tube (41) d'une prise d'entrée de pression (39) ouverte sur la chambre de combustion (14), ledit tube contenant un amortisseur acoustique (40).

6. Appareil de combustion dans lequel du combustible et de l'air sont fournis à un brûleur, ledit appareil comprenant un circuit de rétroaction incluant un détecteur de pression (19) qui génère un signal électrique en réponse à des variations de pression qui sont provoquées principalement par la combustion, et un moyen de traitement du signal (20) produisant un signal en opposition de phase sur la base du signal provenant dudit détecteur de pression et appliqué à un moyen de génération d'onde acoustique (42) afin d'annuler lesdites variations de pression par interférence des phases, caractérisé en ce que

ledit moyen de génération d'onde acoustique (42) est disposé dans une chambre de mélange (13) dans laquelle le combustible et l'air sont mélangés du côté amont d'un brûleur afin de générer un son en opposition de phase qui correspond audit signal en opposition de phase, le moyen de traitement du signal (20) comprenant un filtre électrique fixe (33-3) qui corrige une caractéristique de transfert acoustique sur une plage entre ledit moyen de génération d'onde acoustique et ledit détecteur de pression (19) dans un état de combustion, ladite caractéristique de transfert acoustique ayant été identifiée à l'avance dans un état de combustion, et un moyen de traitement adaptatif (34) qui calcule le signal en opposition de phase,

- ledit moyen de traitement adaptatif (34) comprenant un filtre adaptatif (37) qui fonctionne en réponse à la sortie dudit filtre électrique fixe (33-3) par l'intermédiaire d'un circuit de mise à jour de coefficients de filtre (38) de même qu'au signal provenant directement du détecteur de pression, ledit circuit de mise à jour de coefficients de filtre (38) mettant à jour les coefficients du filtre adaptatif, et un moyen destiné à appliquer le signal en opposition de phase dudit moyen de traitement à filtre adaptatif audit moyen de génération d'onde acoustique (42).
7. Appareil de combustion dans lequel du combustible et de l'air sont fournis à un brûleur, ledit appareil comprenant une commande du type à rétroaction incluant un détecteur de pression (19a) qui génère un signal électrique en réponse à des variations de pression qui sont provoquées principalement par la combustion, et un moyen de traitement du signal (20) produisant un signal en opposition de phase sur la base du signal provenant dudit détecteur de pression et appliqué à un moyen de génération d'onde acoustique (42) afin d'annuler lesdites variations de pression par interférence des phases, caractérisé en ce que
- ledit moyen de génération d'onde acoustique (42) destiné à générer le son en opposition de phase est disposé sur le côté supérieur d'un orifice d'évacuation (17), le détecteur de pression (19a) est agencé dans une chambre de combustion, un autre détecteur de pression (19b) est disposé entre l'orifice d'évacuation (17) et ledit moyen de génération d'onde acoustique (42) et à proximité de ceux-ci, le moyen de traitement du signal (20) comprenant un filtre électrique fixe (33-3) qui corrige une caractéristique du transfert acoustique sur une plage entre ledit moyen de génération d'onde acoustique et ledit détecteur de pression (19b) dans un état de combustion, ladite caractéristique de transfert acoustique ayant été identifiée à l'avance dans un état de combustion, un moyen de traitement adaptatif (34) qui calcule le signal en opposition de phase, ledit moyen de traitement adaptatif (34) comprenant un filtre adaptatif (37) qui fonctionne en réponse à la sortie dudit filtre électrique fixe (33-3) par l'intermédiaire d'un circuit de mise à jour de coefficients de filtre (38), de même qu'au signal provenant directement du détecteur de pression, et ledit circuit de mise à jour de coefficients de filtre (38) mettant à jour les coefficients du filtre

adaptatif (37).

8. Appareil de combustion dans lequel du combustible et de l'air sont fournis à un brûleur, ledit appareil comprenant une commande du type à rétroaction incluant un détecteur de pression (19a) qui génère un signal électrique en réponse à des variations de pression qui sont provoquées principalement par la combustion, et un moyen de traitement du signal (20) produisant un signal en opposition de phase sur la base du signal provenant dudit détecteur de pression et appliqué à un moyen de génération d'onde acoustique (42) afin d'annuler lesdites variations de pression par interférence des phases, caractérisé en ce que
- une chambre de mélange est agencée, dans laquelle du combustible et de l'air sont mélangés, ledit moyen de génération d'onde acoustique (42) destiné à générer le son en opposition de phase est disposé au niveau du côté supérieur d'un orifice d'évacuation (17), et le détecteur de pression (19a) détecte la variation de pression provoquée par la combustion soit dans la partie de brûleur (13), soit dans une conduite d'évacuation (16) pour destinée à acheminer le gaz d'évacuation de la combustion vers l'orifice d'évacuation (17), un autre détecteur de pression (19b) est disposé entre l'orifice d'évacuation (17) et ledit moyen de génération d'onde acoustique (42) et à proximité de ceux-ci, le moyen de traitement du signal (20) comprenant un filtre électrique fixe (33-3) qui corrige une caractéristique de transfert acoustique sur une plage entre ledit moyen de génération d'onde acoustique et ledit second détecteur de pression (19b) dans un état de combustion, ladite caractéristique de transfert acoustique ayant été identifiée à l'avance dans un état de combustion, un moyen de traitement adaptatif (34) qui calcule le signal en opposition de phase, ledit moyen de traitement adaptatif (34) comprenant un filtre adaptatif (37) qui fonctionne en réponse à la sortie dudit filtre électrique fixe (33-3) par l'intermédiaire d'un circuit de mise à jour de coefficients de filtre (38), de même qu'au signal qui provient directement du détecteur de pression, et ledit circuit de mise à jour de coefficients de filtre (38) mettant à jour les coefficients du filtre adaptatif (37).
9. Appareil de combustion selon l'une quelconque des revendications 6 à 8 comprenant en outre :

un nombre multiple de moyens de génération d'onde acoustique (42) disposés au niveau du bord de l'orifice d'évacuation (17), et un nombre multiple de seconds détecteurs de pression (19b) disposés respectivement entre ledit orifice d'évacuation (17) et ledit moyen de génération d'onde acoustique (42).
